Hierarchy for Scientific Evidence in Medical Studies

On 15 July 1911, 65-year-old Mrs. Jane Decker was struck by lightning while in her house. She had been deaf since birth, but after being struck, she recovered her hearing.

Is this compelling evidence that lightning is a cure for deafness?

Hierarchy for Scientific Evidence in Medical Studies

- Observational study
 - Anecdotal evidence: a short story or an example of an interesting event.
 - Retrospective case-control studies (case-control)
 - Prospective cohort studies
- Experiment
 - Randomized clinical trials

Hierarchy for Scientific Evidence in Medical Studies

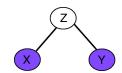

${\sf Smoking} \quad \to \quad {\sf lung \ cancer}$

- Anecdotal evidence example: My uncle smoke and he got lung cancer.
- Retrospective case-control study example: 100 lung cancer patients and 100 normal control were enrolled; then smoking history for each participants was examined.
- Prospective cohort study example: 100 smokers and 100 nonsmoker were enrolled, then were followed up to determine whether they developed lung cancer.
- Randomized clinical trial example: Participants were randomized to receive low-nicotine cigarette or regular cigarette; then were followed-up to determine whether they developed lung cancer.

Confounding: Ice cream consumption and drowning death

A researcher looked into a public database from a southern city, and found an association between ice-cream consumption and number of drowning deaths for a given period. He concluded that ice cream could cause drowning.

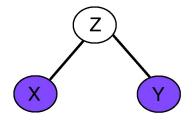

Do you agree? Why do you think the researcher found such association?

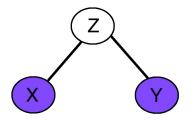

- In epidemiological terms, Z is a "confounder" of the relationship of Y with X if Z is related to both X and Y and Z is not in the causal pathway between X and Y.
- In statistical terms, Z is a "confounder" of the relationship of Y with X if it is not in the causal pathway between X and Y and the X coefficient changes when Z is added to a regression of Y on X.
- Example: Chopsticks gene

Once upon a time, an ethnogeneticist decided to figure out why some people eat with chopsticks and others do not. His experiment was simple. He rounded up several hundred students from a local university, asked them how often they used chopsticks, then collected buccal DNA samples and mapped them for a series of anonymous and candidate genes.

The results were astounding. One of the markers, located right in the middle of a region previously linked to several behavioral traits, showed a huge correlation to chopstick use, enough to account for nearly half of the observed variance. When the experiment was repeated with students from a different university, precisely the same marker lit up. Eureka! The delighted scientist popped a bottle of champagne and quickly submitted an article to Molecular Psychiatry heralding the discovery of the 'successful-use-of-selected-hand-instruments gene' (SUSHI).

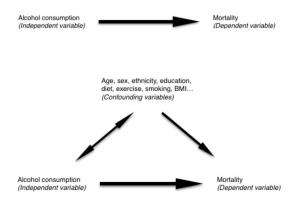

To control for potential confounding effect, we need to stratified by racial groups and perform the analysis within each group.

$$E(Y) = \beta_0 + \beta_1 X \tag{1}$$

$$E(Y) = \beta_0^* + \beta_1^* X + \beta_2 Z$$
 (2)

Compare β_1 and β_1^* in model (1) and (2). If Z is a confounding variable, then β_1^* will be very different from β_1 .

- Variables that are correlated with both the explanatory and response variables can distort the estimated effect
- One strategy to adjust for confounding variables is to stratify by the confounder and then combine the strata-specific estimates
 - Requires appropriately weighting the strata-specific estimates
- Unnecessary stratification reduces precision
- Many confounder combinations, and large number of strata: propensity score
