STAT 516 Lec 05

One-way analysis of variance (ANOVA)

Karl Gregory

2025-02-25

Rust inhibitors example

Data from Kutner et al. (2005).

Ten experimental units assigned to each of four brands of rust inhibitors.

```
link <- url("https://people.stat.sc.edu/gregorkb/data/KNNLrust.txt")
rust <- read.csv(link,col.names=c("score","brand","rep"),sep = "", header = FALSE)
head(rust)</pre>
```

```
score brand rep
1 43.9 1 1
2 39.0 1 2
3 46.7 1 3
4 43.8 1 4
5 44.2 1 5
6 47.7 1 6
```

Do the brands differ in effectiveness? Is there a best brand?

Randomized experiments comparing treatments

Start with N experimental units (EUs), e.g. subjects, mice, etc.

Randomly assign each EU to one of a treatment groups. # treatment groups.

Measure on each EU after treatment a response Y.

HI # EU:

Compute the average of the responses in each treatment group...

Questions we'd like to answer:

- Is the response mean the same in all treatment groups?
- If not, then which pairs of means are different?

One-way ANOVA setup

Consider the model
$$Y_{ij} = \mu + \tau_i + \varepsilon_{ij}, \quad j = 1, \dots, n_i, \quad i = 1, \dots, a,$$
 where
$$Y_{ij} = \mu + \tau_i + \varepsilon_{ij}, \quad j = 1, \dots, n_i, \quad i = 1, \dots, a,$$

where

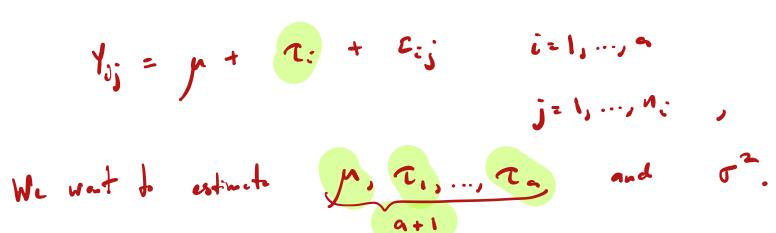

- $igwedge Y_{i\,i}$ is the response for EU j in treatment group i.
- μ represents an everall or baseline mean.
- τ_i is the treatment effect for treatment i.
- The $arepsilon_{ij}$ are independent Normal $(0,\sigma^2)$ error terms.
- lacktriangle The n_i are the numbers of replicates in the treatment groups. "4 $\stackrel{\scriptscriptstyle \bullet}{\scriptstyle \bullet}$ 10

Of central interest are the hypotheses

$$H_0$$
: $au_i=0$ for all i versus H_1 : At least one au_i is nonzero.

If we reject H_0 , we may wish to sort/compare the treatments.

Identifiability constraint in the treatment effects model

The model has a+1 parameters to describe a treatment means.

To identify μ , τ_1,\ldots,τ_a uniquely, we typically set $\tau_1=0$.

This is what most goftware does.

Alternative "cell means model" setup

An alternate version of the model is "cell means"

$$Y_{ij} = \mu_i + \varepsilon_{ij}, \quad j=1,\dots,n_i, \quad i=1,\dots,a,$$
 Let
$$\beta_i = \overline{\gamma}_i.$$

- where
 - $igwedge Y_{ij}$ is the response for EU j in treatment group i.
 - μ_i represents the mean of treatment group i.
 - The ε_{ij} are error terms distributed as Normal $(0, \sigma^2)$.

In this version of the model the central hypotheses become

$$H_0 \colon \mu_1 = \dots = \mu_a \quad \text{ versus } \quad H_1 \colon \mu_i \neq \mu_i' \text{ for some } i \neq i'.$$

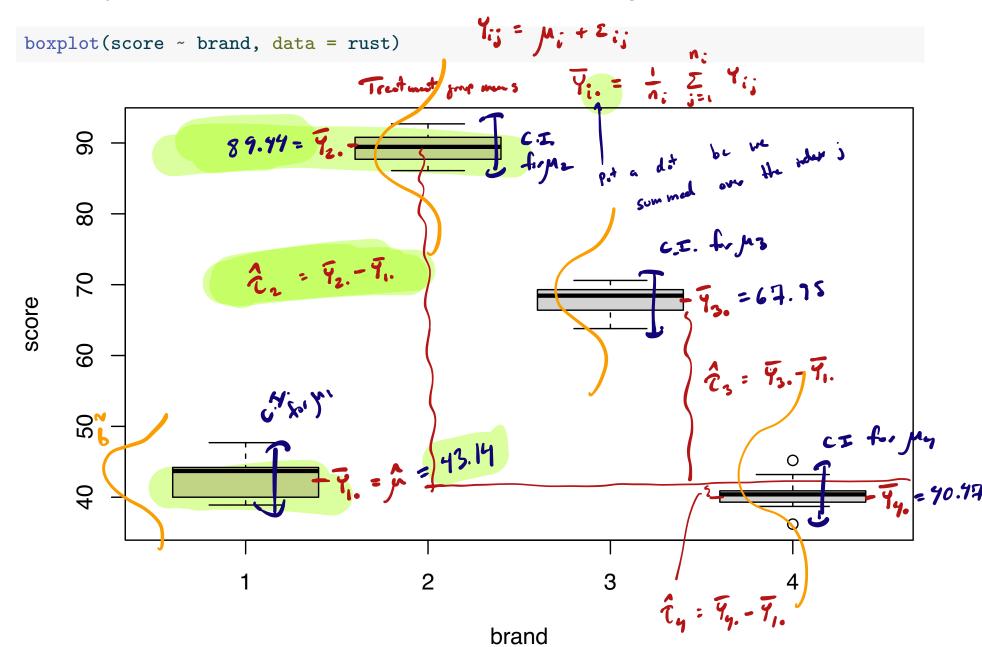

Goals in one-way ANOVA

Under the one-way ANOVA setup

$$Y_{ij}=\mu+\tau_i+\varepsilon_{ij},\quad j=1,\dots,n_i,\quad i=1,\dots,a,$$
 where $\varepsilon_{ij}\stackrel{\rm ind}{\sim} {\rm Normal}(0,\sigma^2)$, we wish to

- Visualize the data.
- **V** Estimate the parameters $\mu, \tau_1, \dots, \tau_a$.
- S. Estimate the error term variance σ^2 .
- 4. Decompose the variation in the Y_{ij} as signal plus noise.
- Test whether there is any difference in treatment group means.
- 6. Sort/compare the treatment means if there is any difference.
- 7. Check whether the model assumptions are satisfied.

Visually compare the means of several treatment groups with boxplots.

Treatment effect estimation in one-way ANOVA

For each i = 1, ..., a define the observed treatment group mean as

Uses Ti. es beadine

$$\bar{Y}_{i.} = \frac{1}{n_i} \sum_{j=1}^{n_i} Y_{ij}.$$

Then, setting $au_1=0$, estimate μ and au_2,\dots, au_a as

$$\widehat{\mu} = \bar{Y}_{1.} \quad \text{and} \quad \widehat{\tau}_i = \underline{\bar{Y}}_{i.} - \bar{Y}_{1.} \quad \text{for } i = 2, \dots, a.$$

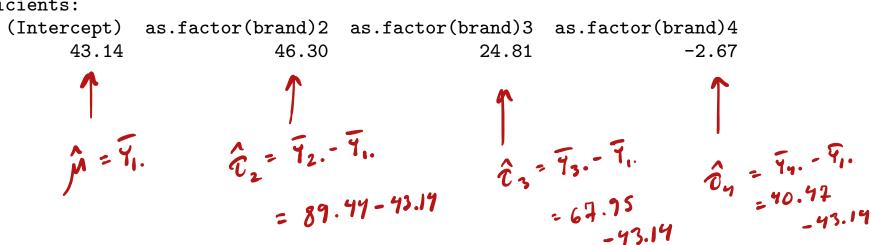

- So treatment group 1 is regarded as a baseline, where:
 - 1. The baseline has estimated mean $\hat{\mu}$.
 - 2. The estimates $\hat{\tau}_2, \dots, \hat{\tau}_a$ are deviations from the baseline.
- One obtains the fitted values $\hat{Y}_{ij} = \hat{\mu} + \hat{\tau}_i = \bar{Y}_i$ for $i=1,\ldots,a$. Filly value as just the gray mass. $\hat{Y}_i + (\hat{Y}_i, -\hat{Y}_i) = \hat{Y}_i$.

Use lm() with as.factor() to fit the one-way ANOVA model.

```
# use as.factor() to designate brand as a "factor"
lm_out <- lm(score ~ as.factor(brand), data = rust)
lm_out</pre>
```

Call: lm(formula = score ~ as.factor(brand), data = rust)

Coefficients:

See how $\hat{\mu},\hat{\tau}_2,\hat{\tau}_3,\hat{\tau}_4$ are related to $\bar{Y}_1,\bar{Y}_2,\bar{Y}_3,\bar{Y}_4$.

```
# compute the group means
aggregate(rust$score, by = list(rust$brand), FUN = mean)
```

```
Group.1 x
1 1 43.14
2 2 89.44
3 67.95
4 40.47
```

Estimation of the error term variance σ^2

As in linear regression, define the

- in linear regression, define the $\underbrace{\text{fitted values } \hat{Y}_{ij} \text{ as } \hat{Y}_{ij} = \bar{Y}_{i.} \text{ for } j = 1, \ldots, n_i, \text{ and the }}_{\text{clusts } \hat{\varepsilon}_{ii} \text{ as } \hat{\varepsilon}_{ij} = Y_{ij} \bar{Y}_{i.}}$

$$\hat{\varepsilon}_{ij} = Y_{ij} - \hat{Y}_{ij}$$
$$= Y_{ij} - \bar{Y}_{i}$$

for
$$j = 1, ..., n_i$$
, $i = 1, ..., a$.

Then an unbiased estimator of σ^2 is given by

$$\hat{\sigma}^2 = \frac{1}{N-a} \sum_{i=1}^a \sum_{j=1}^{n_i} \hat{\varepsilon}_{ij}^2 = \frac{1}{N-a} \sum_{i=1}^a \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y_{i.}})^2.$$
 Divide by $N-a$ since the N residuals depend on a estimated quantities...
$$N = \sum_{i=1}^a \sum_{j=1}^n (Y_{ij} - \bar{Y_{i.}})^2.$$

```
tab <- cbind(rust$brand,rust$score,lm_out$fitted.values,lm_out$residuals)
colnames(tab) <- c("brand", "score", "Fitted value", "Residual")</pre>
head(tab, n = 13)
                                 Y_{ij} - \hat{Y}_{ij} = Y_{ij} - \bar{Y}_{i}.

```

Sums of squares in the one-way ANOVA model

As in linear regression we decompose the variation in the Y_{ij} by defining:

- Total sum of squares: $SS_{Tot} = \sum_{i=1}^{a} \sum_{j=1}^{n_i} (Y_{ij} \bar{Y}_{..})^2$ (Basically just Permission SS')

 Treatment sum of squares: $SS_{Trt} = \sum_{i=1}^{a} n_i (\bar{Y}_{i.} \bar{Y}_{..})^2 = \sum_{i=1}^{a} \sum_{j=1}^{n_i} (\bar{Y}_{i.} \bar{Y}_{..})^2 = \sum_{i=1}^{a} \sum_{j=1}^{n_i} (\bar{Y}_{i.} \bar{Y}_{..})^2 = \sum_{i=1}^{a} \sum_{j=1}^{n_i} (\bar{Y}_{i.} \bar{Y}_{..})^2 = \sum_{i=1}^{n_i} \sum_{j=1}^{n_i} (\bar{Y}_{i.} \bar{Y}_{..})^2 = \sum_{$
- Error sum of squares: $\mathrm{SS}_{\mathrm{Error}} = \sum_{i=1}^a \sum_{j=1}^{n_i} (Y_{ij} \bar{Y}_{i.})^2$ \vdots \vdots $(\bar{Y}_{i.} \bar{Y}_{.})$ the above, $\bar{Y}_{..}$ denotes the overall mean defined $\hat{Y}_{..}$

In the above, $Y_{...}$ denotes the overall mean, defined as $\overline{q}_{...}$

$$\bar{Y}_{..}=N^{-1}\sum_{i=1}^a\sum_{j=1}^{n_i}Y_{ij}, \quad \text{where } N=n_1,\ldots,n_a.$$
 The mass of all the response value.

We have $SS_{Tot} = SS_{Trt} + SS_{Error}$.

Note that $\mathrm{SS}_{\mathrm{Trt}}$ is computed just like $\mathrm{SS}_{\mathrm{Reg}}$ in linear regression.

We again define
$$R^2 = rac{
m SS_{Trt}}{
m SS_{Tot}}$$
 .

Sampling distributions of our sums of squares

The SS, appropriately scaled, follow chi-square distributions:

where ϕ_{Tot} and ϕ_{Trt} are noncentrality parameters.

The mean squares in the one-way ANOVA model

Dividing $\mathrm{SS}_{\mathrm{Trt}}$ and $\mathrm{SS}_{\mathrm{Error}}$ by their dfs, we define:

- Treatment mean square: $MS_{Trt} = \frac{SS_{Trt}}{a-1}$
- Error mean square: $MS_{Error} = \frac{SS_{Error}}{N-a}$

The ratio $F_{
m stat} = {{
m MS}_{
m Trt} \over {
m MS}_{
m Error}}$ has an F distribution.

The Analysis of Variance (ANOVA) table

We often present the SS, df, and MS values in a table like this:

Source	Df	SS	MS	F value	p-value
Treatment Error	a-1 $N-a$	${ m SS}_{ m Trt} \ { m SS}_{ m Error}$	${ m MS}_{ m Trt}$ ${ m MS}_{ m Error}$	F_{stat}	$P(F > F_{\rm stat})$
Total	N-1	$\mathrm{SS}_{\mathrm{Tot}}$	Ellor		

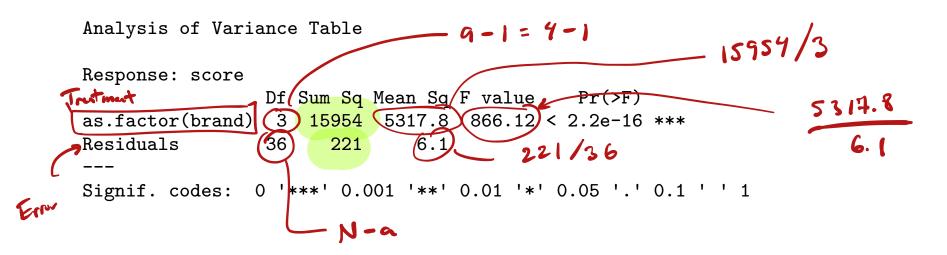

In the table $F_{
m stat} = rac{
m MS_{Trt}}{
m MS_{Error}}.$

The p-value is based on $F \sim F_{a-1,N-a}$.

$$N=40$$
 $a=4$

Obtain the ANOVA table with the anova() function on the lm() output.

anova(lm_out)

Source	Df	SS	MS	F value	p-value	
Treatment Error Total	$egin{array}{c} a-1 \ N-a \ N & 1 \end{array}$	${ m SS}_{ m Trt} \ { m SS}_{ m Error} \ { m SS}_{ m Tot}$	${ m MS_{Trt} \atop MS_{Error}}$	$F_{ m stat}$	$P(F>F_{\rm stat})$	

Testing whether there is any difference in treatment means

In the one-way ANOVA model we wish to test

Tretunt alobe
$$H_0$$
: $au_i=0$ for all i versus H_1 : At least one au_i is nonzero.

$$H_1$$
: At least one τ_i is nonzero

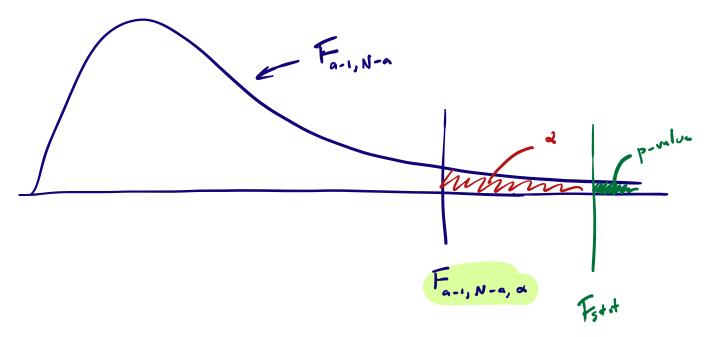

Cell mems: Ho: $\mu_1 = \cdots = \mu_n$ verses H: $\mu_i \neq \mu_j$ for some if j

We use the overall F test of significance: ($\mu_0 \neq \mu_1 \neq \mu_2 \neq \mu_3 \neq \mu_4 \neq \mu_5 \neq \mu_5 \neq \mu_4 \neq \mu_5 \neq \mu_4 \neq \mu_5 \neq \mu_4 \neq \mu_5 \neq \mu_5 \neq \mu_4 \neq \mu_5 \neq \mu_6 \neq \mu$

1. Compute
$$F_{\text{stat}} = \frac{\text{MS}_{\text{Trt}}}{\text{MS}_{\text{Error}}}$$

- 2. Reject H_0 at α if $F_{\text{stat}} > F_{a-1,N-a,\alpha}$.
- 3. Obtain p-value as $P(F>F_{\rm stat})$, where $F\sim F_{a-1,N-a}$.

The value of $F_{\rm stat}$ and the p-value are printed in the summary() output.

Right Ho: M====

when Fold

is large Why?

$$F_{aht} = \frac{MS_{7t+}}{MS_{Emi}} = \frac{SS_{727}}{SS_{Emi}}/(n-1)$$

$$= \frac{2}{121} n_1 (\overline{Y_{i,-}} - \overline{Y_{i,-}})^2/(n-1)$$

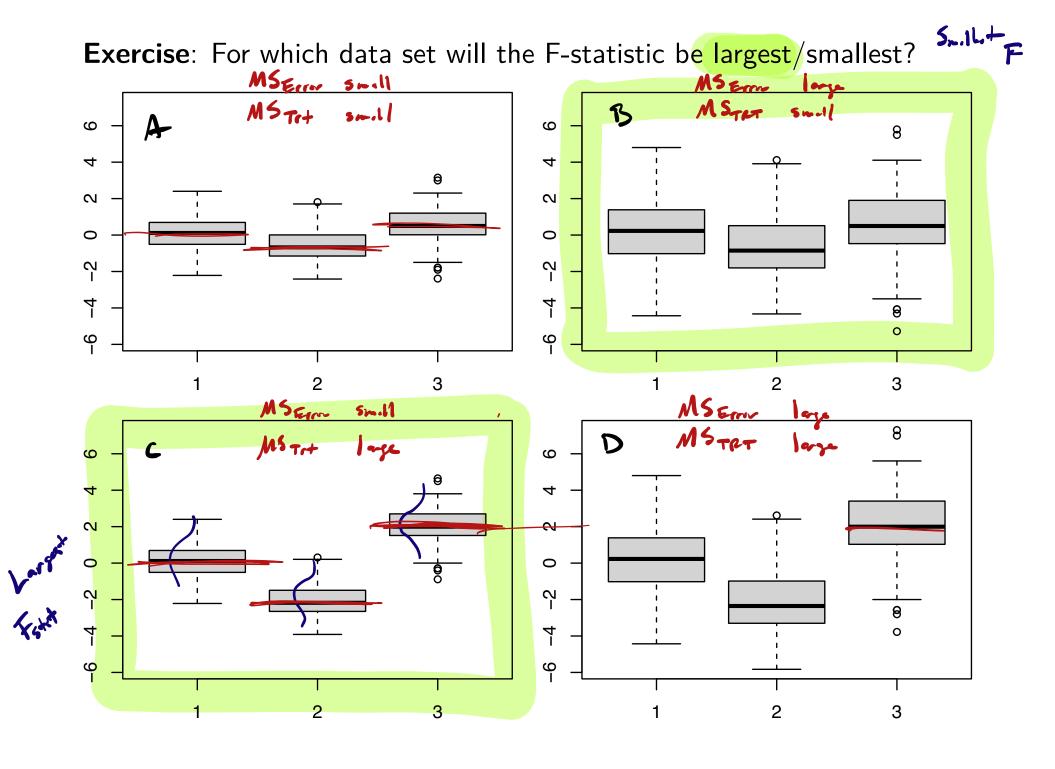

$$= \frac{2}{121} \sum_{i=1}^{n_1} (\overline{Y_{i,j}} - \overline{Y_{i,-}})^2/(N-1)$$

Variation in individual responses around the

Interpretation of F statistic

Note that F_{stat} is a ratio of the form

Between treatment variation Within treatment variation

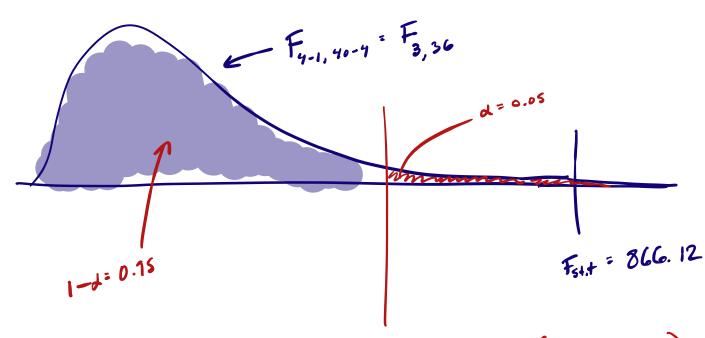

Exercise: Compute $F_{\rm stat}$ for the rust data using the summary info:

$$SS_{Em.} = 9 \cdot (3.00)^{2} + 9 \cdot (2.22)^{2} + 9(2.14)^{2} + 9(2.44)^{2} = 221$$

$$\overline{9}_{..} = (93.19 + 89.49 + 69.15 + 90.97)/9 = 60.25$$

$$SSTPT = \frac{2}{121} n_1 (\bar{\gamma}_1 - \bar{\gamma}_{..})^2 = 10 (43.19 - 60.25)^2 + 10 (89.99 - 60.25)^2 + 10 (67.75 - 60.25)^2 + 10 (40.99 - 60.25)^2$$

$$F_{sh}$$
 = $\frac{15,559}{221/(40-4)}$ = 866.12

$$F_{3,56,0.05} = \begin{cases} f(0.95, 3, 36) \\ = 2.87 \end{cases}$$

Some CI formulas (without familywise adjustment)

In the cell-means formulation of the model

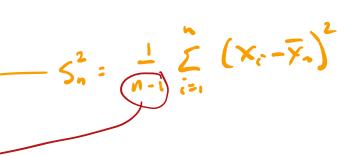

$$Y_{ij} = \mu_i + \varepsilon_{ij}, \quad j = 1, \dots, n_i, \quad i = 1, \dots, a,$$

where $\mu_i = \mu + \tau_i$, we have the following CI formulas:

$$\hat{\beta}^2 = \frac{1}{N-\alpha} \sum_{i=1}^{n} \sum_{j=1}^{n} \hat{\xi}_{ij}$$

Target

```

[1] 44.05259 48.54741

Post-hoc comparisons of means

- If we reject H_0 : $\mu_1 = \cdots = \mu_a$, then we may wish to compare means.
- Call such comparisons post-hoc as we do them *after* the F-test.
- We may wish to compare several pairs of means, which is like testing several hypotheses at once.
- When several hypotheses are tested at once, the familywise Type I error rate is the probability that any Type I error is committed.
- ► We discuss two methods for post-hoc comparisons of means which control the familywise Type I error rate.

Comparing all pairs of means

- We want to build a CI for $\mu_i \mu_{i'}$ for all pairs $i \neq i'$.
- Suppose the design is balanced, i.e. $n_i = n$ for all $i = 1, \dots, a$.
- ▶ If we build for all $i \neq i'$ the ordinary $(1 \alpha) \times 100\%$ Cls

$$\bar{Y}_{i.} - \bar{Y}_{i'.} \pm t_{a(n-1),\alpha/2} \hat{\sigma} \sqrt{2/n},$$

each one will cover its target with probability $1-\alpha$.

lacksquare But now we want *simultaneous* coverage with probability 1-lpha, i.e.

$$P(\cap_{i\neq i'}\{\operatorname{CI \ for \ } \mu_i-\mu_{i'} \ \operatorname{captures \ target}\})=1-\alpha.$$

Above probability is called the familywise coverage.

The venerable John Tukey

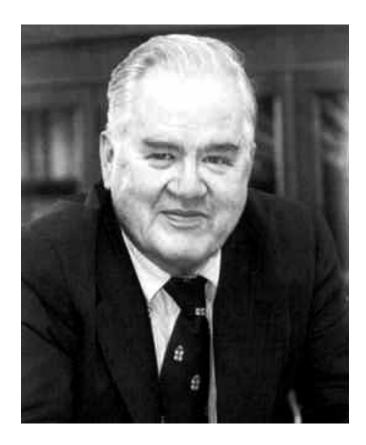

Figure 1: John Tukey, 1915 – 2000

Multiple comparisons of means with Tukey's HSD

- Suppose the design is balanced, i.e. $n_i = n$ for all $i = 1, \dots, a$.
- Suppose we could find the value $q_{a,a(n-1),\alpha}$ such that

$$P\left(\max_{i\neq i'}\left\{\frac{|(\bar{Y}_{i.}-\bar{Y}_{i'.})-(\mu_i-\mu_{i'})|}{\hat{\sigma}/\sqrt{n}}\right\}\leq q_{a,a(n-1),\alpha}\right)=1-\alpha.$$

lacktriangle Then with probability $1-\alpha$ the CIs

$$\bar{Y}_{i.} - \bar{Y}_{i'.} \pm q_{a,a(n-1),\alpha} \hat{\sigma} / \sqrt{n}$$

will simultaneously cover the targets $\mu_i - \mu_{i'}$ for all $i \neq i'$. Show!

- lacksquare Tukey made tables of the values $q_{a,a(n-1),\alpha}$.
- Can use the simultaneous intervals to sort/compare the means.

Table A.6 Critical Values of the Studentized Range, for Tukey's HSD.

Table produced using the SAS System using function PROBMC('SRANGE', $1 - \alpha$, df, T).

Figure 2: Table A.6 from Mohr, Wilson, and Freund (2021)

For the rust data we have n=10 and a=4.

At $\alpha=0.05$ we have $q_{a,a(n-1),\alpha}=q_{4,36,0.05}\approx 3.85$ from table.

Obtain exact value with qtukey (.95,4,36) = 3.8087984.

Build the Tukey HSD CI for $\mu_2 - \mu_1$.

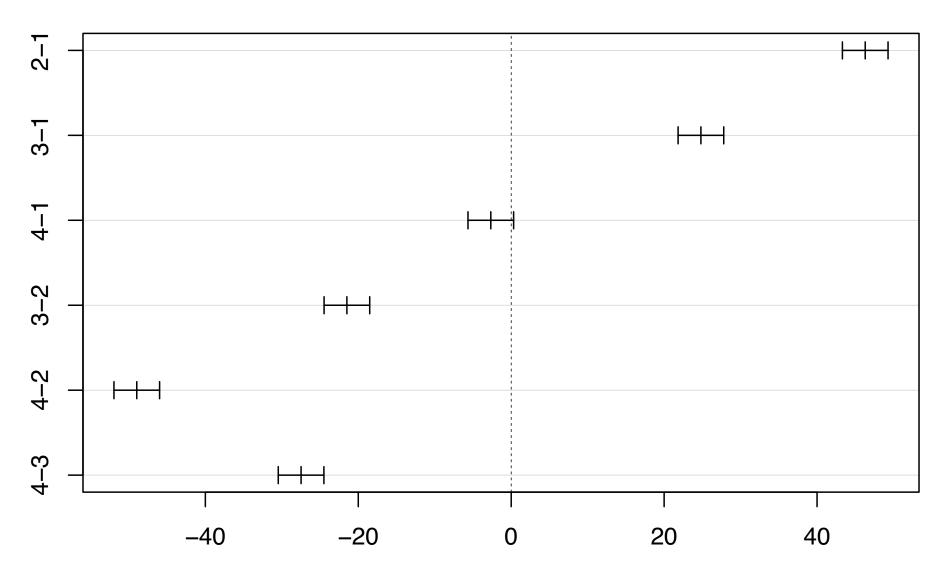

```
n <- 10
a <- 4
MSE <- sum(lm_out$residuals^2) / ( a*(n-1))
y1bar <- mean(rust$score[rust$brand == 1])
y2bar <- mean(rust$score[rust$brand == 2])
me <- qtukey(.95,a,a*(n-1)) * sqrt(MSE) / sqrt(10)
lo21 <- y2bar - y1bar - me
up21 <- y2bar - y1bar + me
c(lo21,up21)</pre>
```

[1] 43.31554 49.28446

Use TukeyHSD() on aov() output to obtain the simultaneous Cls.

```
# must use the aov() function instead of the lm() function
aov out <- aov(score ~ as.factor(brand), data = rust)
TukeyHSD(aov_out)
  Tukey multiple comparisons of means
   95% family-wise confidence level
Fit: aov(formula = score ~ as.factor(brand), data = rust)
$`as.factor(brand)`
     diff
                  lwr
                              upr
                                     p adj
2-1 46.30 43.315536 49.2844635 0.0000000

4-3 -27.48 -30.464464 -24.4955365 0.0000000
```

95% family-wise confidence level

Differences in mean levels of as.factor(brand)

Comparison of treatments with a baseline treatment

- It may be that not all pairwise comparisons are of interest.
- Then Tukey's method is too conservative (CIs wider than necessary).
- > Say we want to compare all treatments to a "baseline" treatment.
- \blacktriangleright Build CIs for $\mu_i \mu_1$, i = 2, ..., a, 1 the baseline treatment.
- ▶ This makes a-1 Cls instead of $\binom{a}{2}$ Cls.
- Can use Dunnett's method, Dunnett (1964).

The equally venerable Charles Dunnett

Figure 3: Charles Dunnett, 1921 – 2007 (Canadian, served in WWII, photo taken in Belgium)

Dunnett's method for comparisons with a baseline

- Assume $n_i = n$ for all i (balanced case).
- Given a value $d_{n,a(n-1),\alpha}$ such that

$$P\left(\max_{2\leq i\leq a}\left|\frac{(\bar{Y}_{i.}-\bar{Y}_{1.})-(\mu_i-\mu_1)}{\hat{\sigma}\sqrt{2/n}}\right|\leq d_{n,a(n-1),\alpha}\right)=1-\alpha,$$

with probability $1-\alpha$ the CIs

$$\bar{Y}_{i.} - \bar{Y}_{1.} \pm d_{n,a(n-1),\alpha} \hat{\sigma} \sqrt{2/n}$$

will simultaneously cover the targets $\mu_i - \mu_1$ for all $i = 2, \dots, a$.

- Dunnett made tables of the values $d_{n,a(n-1),\alpha}$.
- Cannot sort all the means after Dunnett's.

Table A.5 Critical Values for Dunnett's Two-Sided Test of Treatments versus Control.

Figure 4: Table A.5 from Mohr, Wilson, and Freund (2021)

Rust inhibitor data (cont)

For the rust data we have n=10 and a=4.

At $\alpha = 0.05$ we have $d_{a,a(n-1),\alpha} = d_{4,36,0.05}$.

Use value 2.44 in the table (should be close).

Treat Brand 1 as the baseline and make comparisons with Dunnett's.

```
# just show the comparison of treatment 2 to the baseline
y1bar <- mean(rust$score[rust$brand == 1])
y2bar <- mean(rust$score[rust$brand == 2])

me <- 2.44 * sqrt(MSE) * sqrt(2/10) # margin of error for Dunnett's

lo21 <- y2bar - y1bar - me
up21 <- y2bar - y1bar + me

c(y2bar - y1bar,lo21,up21)</pre>
```

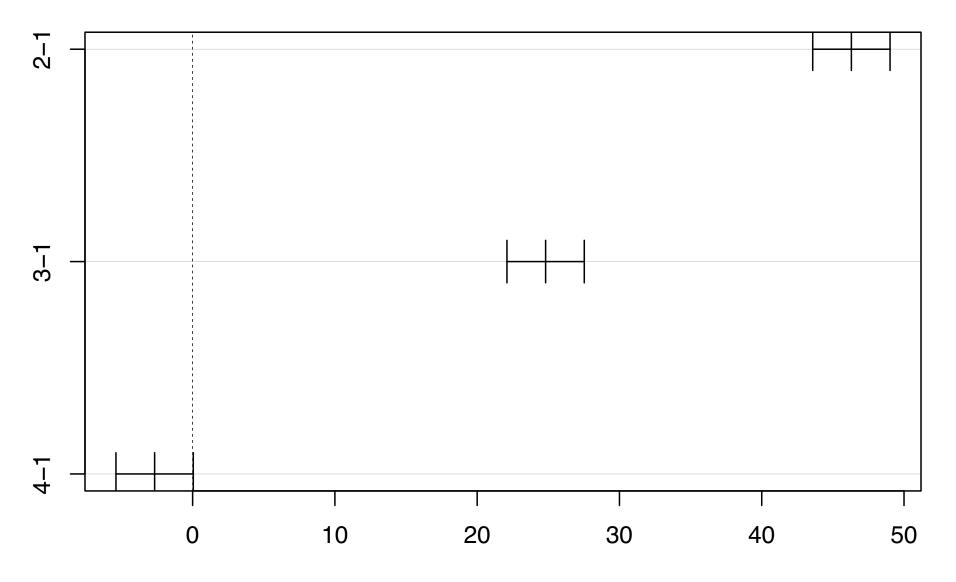

[1] 46.30000 43.59615 49.00385

Rust inhibitor data (cont)

Use DunnettTest() from R package DescTools.

```
library(DescTools) # first time run install.packages("DescTools")
Dunnett_out <- DunnettTest(score ~ as.factor(brand), data = rust, control = "1")</pre>

```

95% family-wise confidence level

Differences in mean levels of 1

Dunnett's vs Tukey's

- Tukey's is for comparisons between all pairs of means.
- Dunnett's is for comparison of means with a baseline.
- So Tukey's must make greater adjustments to control the familywise Type I error.
- Therefore Tukey intervals will be wider than Dunnett intervals.
- Tukey's allows you to sort the means, while Dunnett's does not.
- Both methods assume a balanced design, i.e. $n_i = n$ for all i. Modifications for unbalanced designs exist, but are not straightforward to implement in R.

Bonferroni correction

If building B CIs you can ALWAYS use the Bonferroni correction:

- ▶ Build each CI ordinarily, but use α/B instead of α .
- Ensures simultaneous coverage of all CIs with probability $\geq 1 \alpha$.
- lacktriangle True prob of simultaneous coverage may be greater than 1-lpha
- ▶ Bonferroni-corrected CIs will be wider than Dunnett's and wider than Tukey's if used for making those same comparisons.
- Use when we do not know how to adjust for multiple comparisons.

Rust inhibitor data (cont)

Compare Brand 3 to 4 and Brand 1 to 3, using the Bonferroni correction to control the familywise error rate.

```
lower upper 3-4 24.888 30.072 1-3 -27.402 -22.218
```

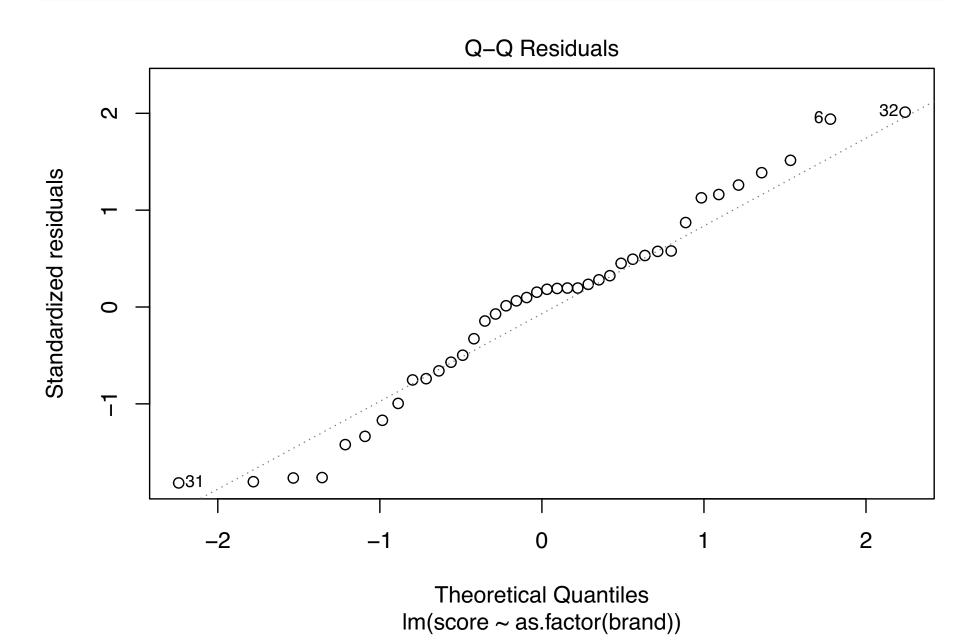

Checking model assumptions

Validity of the foregoing analyses depends on these assumptions:

- 1. The responses are normally distributed around the treatment means (Check QQ plot of residuals).
- 2. The response has the same variance in all treatment groups (Check residuals vs fitted values plot).
- 3. The response values are independent of each other (No way to check; must trust experimental design).

Perception of slope example

Do axis re-scalings affect how we perceive an x-y relationship?

For a single data set with data pairs (X_i,Y_i) , with $X_i \sim \text{Normal}(0,1)$ and $Y_i = \text{Normal}(X_i,1)$ for $i=1,\dots,50$, three scatterplot treatments were constructed:

- 1. "Control" used x and y plotting limits given by the range of the data.
- 2. "X" extended the x-limits by 1.5 in each direction.
- 3. "Y" extended the y-limits by 1.5 in each direction.

Each student in a class was randomly assigned a scatterplot and told to draw with a ruler the best-fitting line through the data. The slope of each student-drawn line was measured and recorded as the response.

Is the response mean the same in the three treatment groups?

An artifact from each treatment group:

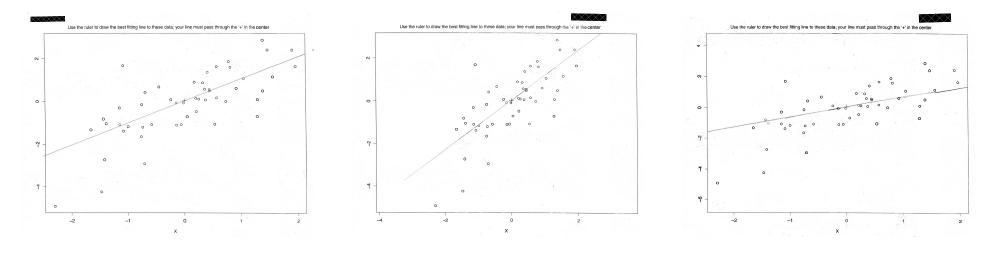

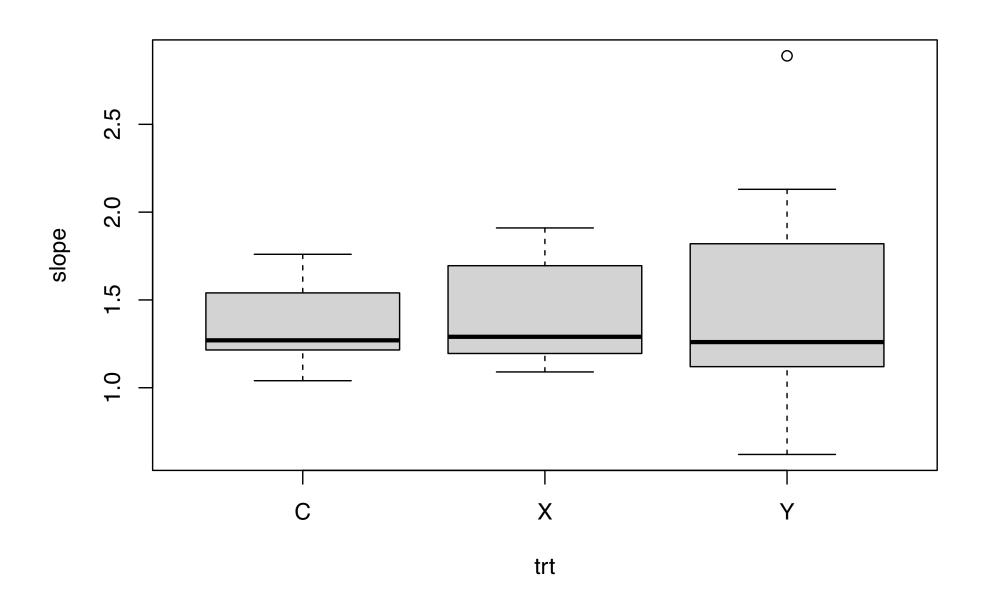

Figure 5: "Control"

Figure 6: "X"

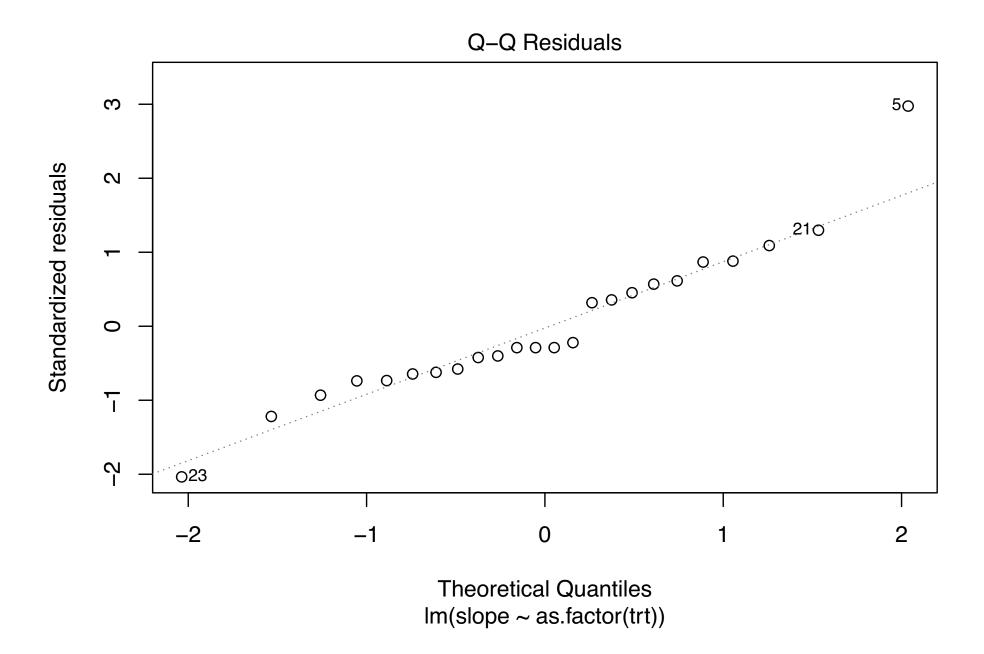

Figure 7: "Y"

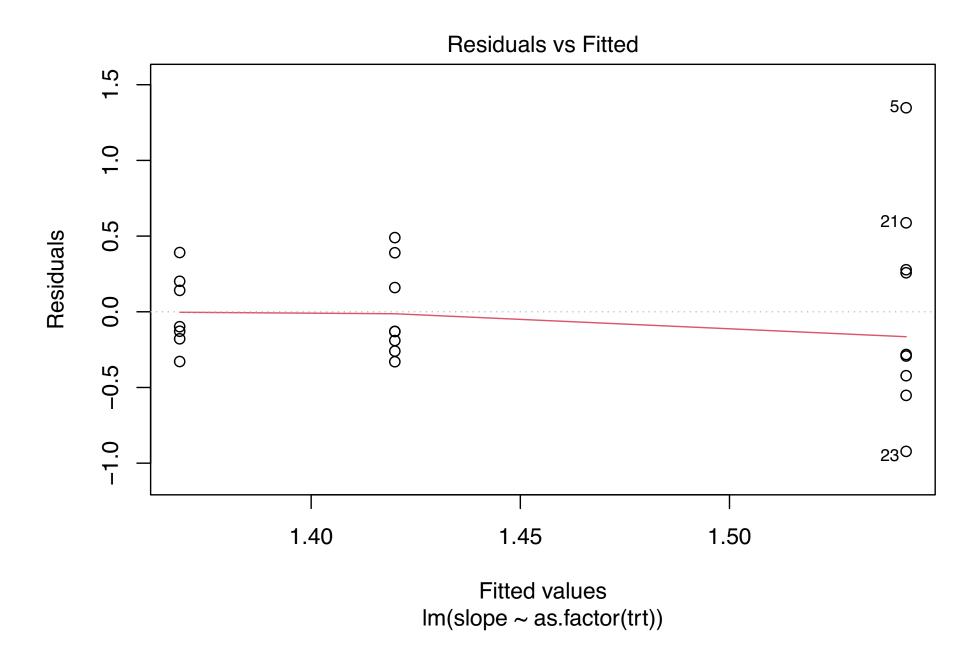

boxplot(slope ~ trt)

```

F-statistic: 0.2818 on 2 and 21 DF, p-value: 0.7572

Levene's test for equality of variances

Checks if the mean magnitude of the residuals is equal across groups:

- 1. Obtain the residuals $\hat{\varepsilon}_{ij}$ from the one-way ANOVA model.
- 2. Treat the absolute values $|\hat{\varepsilon}_{ij}|$ of the residuals as *new* responses.
- 3. Test for equal means of the new responses with the F test.
- So, do the ordinary F-test with the $|\hat{\varepsilon}_{ij}|$ as the responses.

Perception of slope example (cont)

Perform Levene's test:

```
ehat <- lm_slope$residuals</pre>
lm_levene <- lm(abs(ehat) ~ as.factor(trt))</pre>

F-statistic: 4.565 on 2 and 21 DF, p-value: 0.02258
```

Can also use the leveneTest() function in the R package car.

We conclude that the variances are *not* equal across treatment groups.
