Nonparametric regression: N-W and LP smoothers

Karl Gregory

University of South Carolina

These slides are an instructional aid; their sole purpose is to display, during the lecture, definitions, plots, results, etc. which take too much time to write by hand on the blackboard. They are not intended to explain or expound on any material.

Nonparametric inference

Kernel density estimation

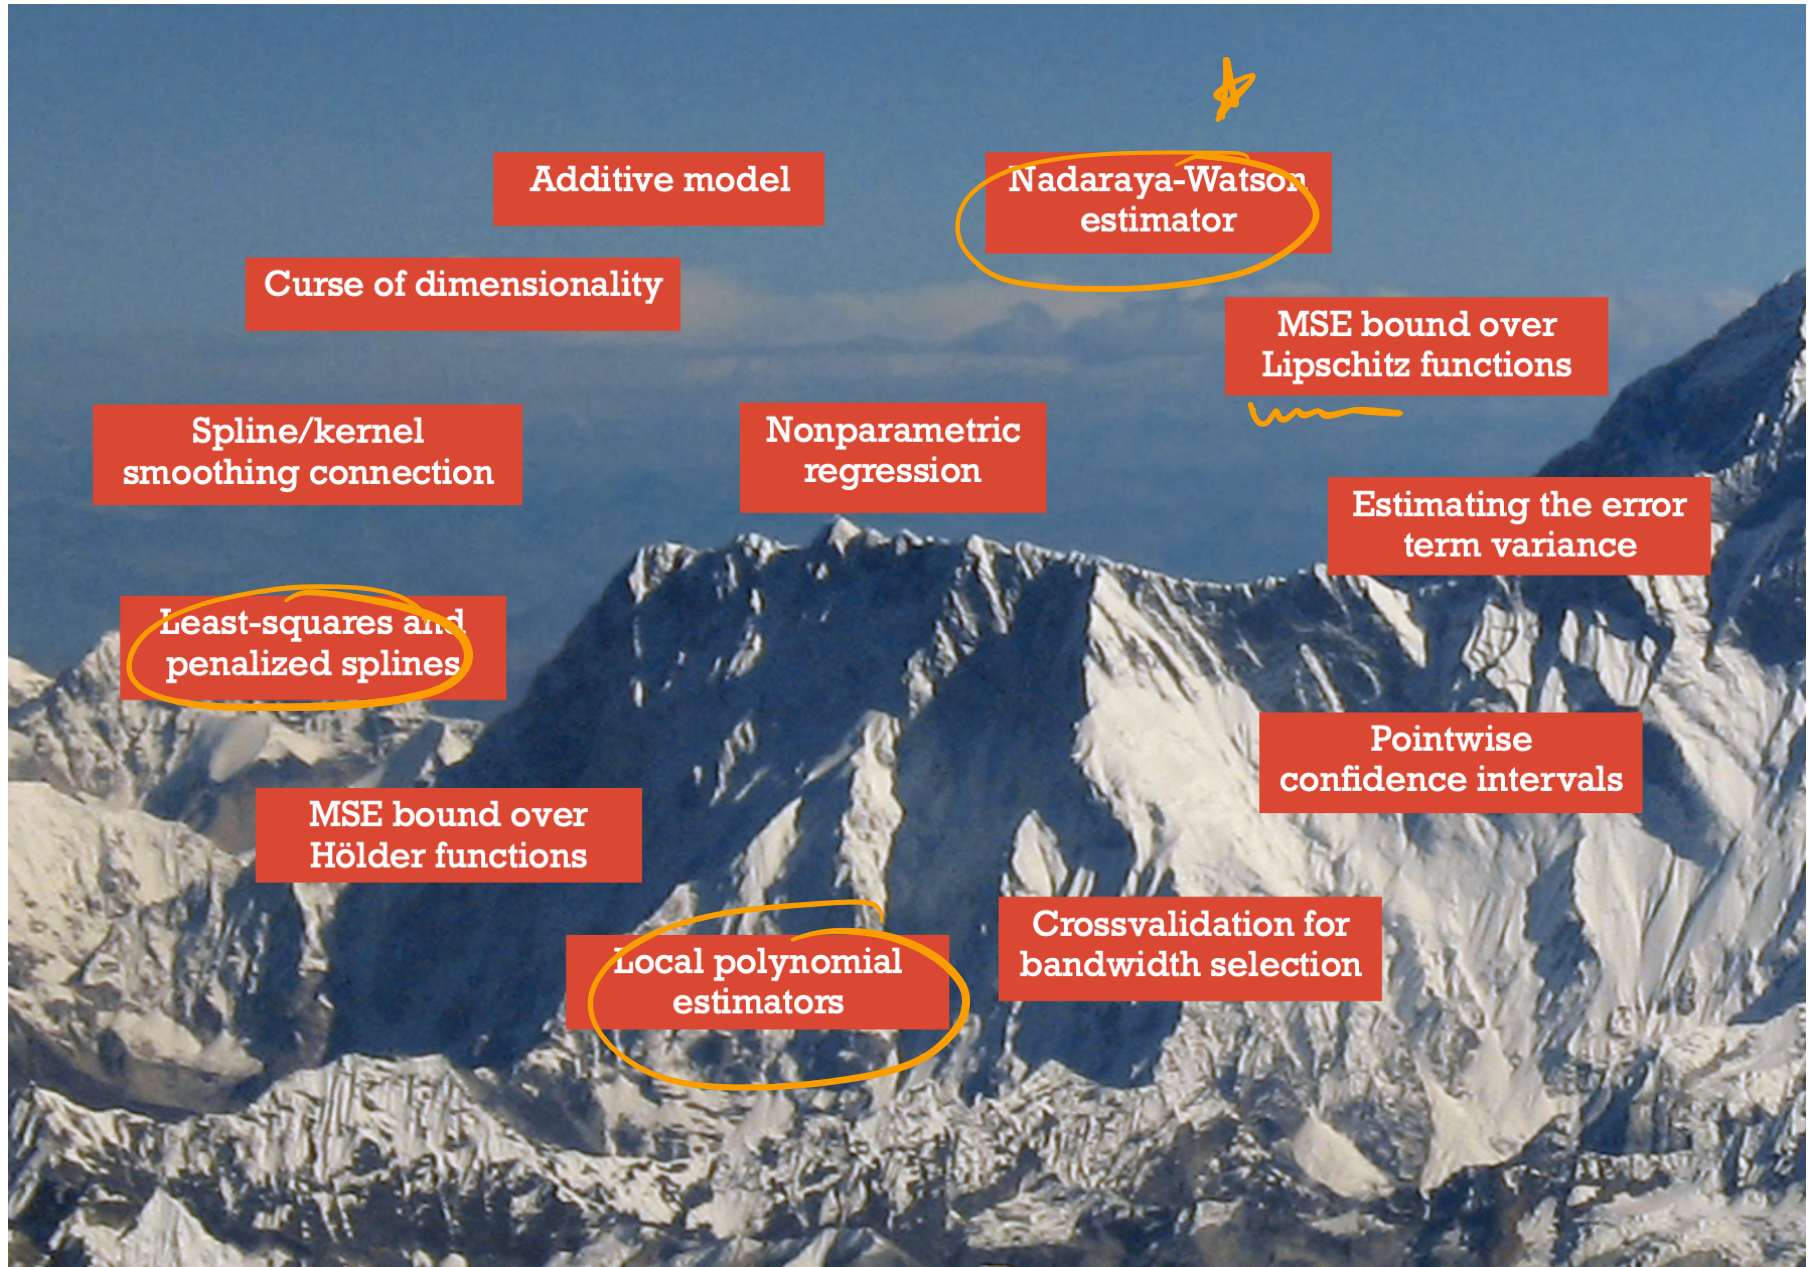

Nonparametric regression

Minimax theory

Bootstrap

cdf estimation

trad nonparm

Additive model

Nadaraya-Watson estimator

Curse of dimensionality

MSE bound over Lipschitz functions

Spline/kernel smoothing connection

Nonparametric regression

Estimating the error term variance

Least-squares and penalized splines

Pointwise confidence intervals

MSE bound over Hölder functions

Local polynomial estimators

Crossvalidation for bandwidth selection

Observe $(X_1, Y_1), \dots, (X_n, Y_n)$ ind. copies of (X, Y) , where

$$Y = m(X) + \varepsilon,$$

$$\varepsilon \perp\!\!\!\perp X, \quad \mathbb{E} \varepsilon = 0, \quad \mathbb{E} \varepsilon^2 = \sigma^2.$$

↑
independent

Goal: Estimate function m , σ^2 .

"local average estimator"

$$\hat{m}(x) = \frac{\sum_{i=1}^n Y_i \mathbb{1}(x-h \leq X_i \leq x+h)}{\sum_{i=1}^n \mathbb{1}(x-h \leq X_i \leq x+h)}$$

$$= \frac{\sum_{i=1}^n Y_i \mathbb{1}\left(-1 \leq \frac{X_i - x}{h} \leq 1\right)}{\sum_{i=1}^n \mathbb{1}\left(-1 \leq \frac{X_i - x}{h} \leq 1\right)}$$

$$= \frac{\sum_{i=1}^n y_i k\left(\frac{x_i - x}{h}\right)}{\sum_{i=1}^n k\left(\frac{x_i - x}{h}\right)},$$

$$k(z) = \mathbb{1}(-1 \leq z \leq 1)$$

Nonparametric regression model

Let $(X_1, Y_1), \dots, (X_n, Y_n)$ be independent realizations of $(X, Y) \in T \times \mathbb{R}$, where

$$Y = m(X) + \varepsilon,$$

where ε is independent of X with $\mathbb{E}\varepsilon = 0$ and $\mathbb{E}\varepsilon^2 = \sigma^2$.

- Note that $m(x) = \mathbb{E}[Y|X = x]$.
- Will assume that m belongs to some class of smooth functions.
- Linear regression assumes $m \in \text{Lin}(T)$, where

$$\text{Lin}(T) = \{m : T \rightarrow \mathbb{R} : m(x) = \beta_0 + \beta_1 x, \text{ for some } \beta_0, \beta_1 \in \mathbb{R}\}.$$

- We will proceed treating X_1, \dots, X_n as deterministic (fixed) in $[0, 1]$.

Consider the “local-average” estimator of m given by

$$\bar{m}_n(x) = \frac{\sum_{i=1}^n Y_i \cdot \mathbf{1}(x - h \leq X_i \leq x + h)}{\sum_{j=1}^n \mathbf{1}(x - h \leq X_j \leq x + h)}$$

for all x , for some $h > 0$.

Discuss: Potential problems? Draw pictures.

Nadaraya-Watson estimator

The *Nadaraya-Watson (N-W)* estimator of m is given by

$$\hat{m}_n^{\text{NW}}(x) = \frac{\sum_{i=1}^n Y_i \cdot K(h^{-1}(X_i - x))}{\sum_{j=1}^n K(h^{-1}(X_j - x))}$$

for all x , for some $h > 0$ and kernel function K .

Exercise: Show that $\hat{m}_n^{\text{NW}}(x)$ is an estimate of $\mathbb{E}[Y|X = x]$ based on

$$\hat{f}_n(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{X_i - x}{h}\right) \quad \text{and} \quad \hat{f}_n(x, y) = \frac{1}{nh^2} \sum_{i=1}^n K\left(\frac{X_i - x}{h}\right) K\left(\frac{Y_i - y}{h}\right).$$

$$\mathbb{E} \left[\frac{Y}{\hat{f}_n(Y|X)} \mid X=x \right] = \int_{\mathbb{R}} y \hat{f}_n(y|x) dy$$

$$= \int_{\mathbb{R}} y \frac{\hat{f}_n(x, y)}{\hat{f}_n(x)} dy$$

$$= \frac{1}{\hat{f}_n(x)} \int_{\mathbb{R}} y \hat{f}_n(x, y) dy$$

$$= \frac{1}{\frac{1}{nh} \sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)} \int_{\mathbb{R}} y \frac{1}{nh^2} \sum_{i=1}^n K\left(\frac{x_i - x}{h}\right) K\left(\frac{y_i - y}{h}\right) dy$$

$$= \frac{\frac{1}{h} \sum_{i=1}^n K\left(\frac{x_i - x}{h}\right) \int_{\mathbb{R}} y K\left(\frac{y_i - y}{h}\right) dy}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

$$u = \frac{y_i - y}{h}$$

$$y = y_i - hu$$

$$dy = -h du$$

$$= \frac{\frac{1}{h} \sum_{i=1}^n K\left(\frac{x_i - x}{h}\right) \int_{\infty}^{-\infty} (y_i - hu) K(u) (-h) du}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

$$= \frac{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right) \int_{-\infty}^{\infty} (y_i - hn) K(u) du}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

$$= \frac{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right) \left(\int_{-\infty}^{\infty} y_i K(u) du - h \int_{-\infty}^{\infty} u K(u) du \right)}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

$= 0$ if K symm. around 0.

$$= \frac{\sum_{i=1}^n y_i K\left(\frac{x_i - x}{h}\right)}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

Exercise: Make plots of the NW estimator as on the previous slide, where

$$m(x) = 5x \sin(2\pi(1 + x)^2), \quad \varepsilon \sim \text{Normal}(0, \sigma^2),$$

under the

- 1 Epinechnikov kernel $K(z) = (3/4)(1 - z^2)\mathbf{1}(|z| \leq 1)$.
- 2 Gaussian kernel $K(z) = 1/\sqrt{2\pi}e^{-z^2/2}$.

We now find a bound for $\text{MSE } \hat{m}_n^{\text{NW}}(x)$ under simple conditions:

(K1) Let K have support on $[-1, 1]$ and let $0 \leq K(u) \leq K_{\max} < \infty \forall u \in \mathbb{R}$.

(D1) Let X_1, \dots, X_n be deterministic such that for some $n_0 > 0$

$$\hat{f}_n(x) = (nh)^{-1} \sum_{i=1}^n K(h^{-1}(X_i - x)) \geq f_{\min} > 0 \quad \text{for all } x \in [0, 1]$$

for all $n \geq n_0$.

Pointwise MSE bound for N-W under Lipschitz smoothness

Under (K1) and (D1), if $m \in \text{Lipschitz}(L)$ on $[0, 1]$, we have

$$\text{MSE } \hat{m}_n^{\text{NW}}(x_0) \leq h^2 \cdot L^2 + \frac{\sigma^2}{nh} \cdot \frac{K_{\max}}{f_{\min}} \quad \text{for all } x_0 \in [0, 1]$$

for all $n \geq n_0$.

$$\Rightarrow h_{\text{opt}} = \text{const. } n^{-1/3} \quad \Rightarrow \text{MSE}_{\text{opt}} \leq \text{const. } n^{-2/3}$$

Exercise:

- 1 Find the weights $W_{ni}(x)$, $i = 1, \dots, n$, such that we can write

$$\hat{m}_n^{NW}(x) = \sum_{i=1}^n W_{ni}(x) Y_i.$$

- 2 Prove the result on the previous slide.
- 3 Find the optimal bandwidth (in terms of minimizing the MSE bound).

$$\textcircled{1} \quad \hat{m}_n^{NW}(x) = \frac{\sum_{i=1}^n Y_i K\left(\frac{X_i - x}{h}\right)}{\sum_{i=1}^n K\left(\frac{X_i - x}{h}\right)} = \sum_{i=1}^n W_{ni}(x) Y_i,$$

where

$$W_{ni}(x) = \frac{K \left(\frac{x_i - x}{h} \right)}{\sum_{j=1}^n K \left(\frac{x_j - x}{h} \right)}$$

② Upper bound for $\text{Var } \hat{m}_n^{NW}(x)$:

$$\text{Var } \hat{m}_n^{NW}(x) = \text{Var} \left(\sum_{i=1}^n W_{ni}(x) \epsilon_i \right)$$

≥ 0 by $K \geq 1$

$$= \sigma^2 \sum_{i=1}^n W_{ni}^2(x)$$

$$\leq \sigma^2 \left(\max_{1 \leq i \leq n} W_{ni}(x) \right) \underbrace{\sum_{i=1}^n W_{ni}(x)}_{=1}$$

$$= \frac{\sigma^2}{nh} \left(\max_{1 \leq i \leq n} \frac{K \left(\frac{x_i - x}{h} \right)}{\underbrace{\frac{1}{nh} \sum_{i=1}^n K \left(\frac{x_i - x}{h} \right)}} \right)$$

$\hat{f}_n(x) \geq f_{\min} > 0$

$$\leq \frac{\sigma^2}{nh} \cdot \frac{K_{\max}}{f_{\min}}$$

Upper bound for $\left| \text{Bias } \hat{m}_n^{NW}(x) \right|$

$$y_i = m(x_i) + \varepsilon_i$$

$$\begin{aligned} \text{Bias } \hat{m}_n^{NW}(x) &= E \hat{m}_n^{NW}(x) - m(x) \\ &= E \sum_{i=1}^n W_{n_i}(x) y_i - m(x) \\ &= \sum_{i=1}^n W_{n_i}(x) m(x_i) - m(x) \\ &= \sum_{i=1}^n W_{n_i}(x) [m(x_i) - m(x)] \end{aligned}$$

$$|m(x) - m(x')| \leq L |x - x'|$$

$$\left| \text{Bias } \hat{m}_n^{NW}(x) \right| \leq \sum_{i=1}^n W_{n_i}(x) \left| m(x_i) - m(x) \right|$$

$$\leq \sum_{i=1}^n W_{n_i}(x) L |x_i - x|$$

$$= \sum_{i: W_{n_i}(x) \neq 0} W_{n_i}(x) L |x_i - x|$$

$$= \sum_{i: W_{n_i}(x) \neq 0} W_{n_i}(x) L h$$

$$= L \cdot h \underbrace{\sum_{i=1}^n W_{n_i}(x)}_{=1}$$

$$= L \cdot h$$

$$W_{n_i}(x) = \frac{K\left(\frac{x_i - x}{h}\right)}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

$$= 0 \Leftrightarrow$$

$$\frac{x_i - x}{h} \notin [-1, 1]$$

$$\Leftrightarrow |x_i - x| > h$$

Plugging in the optimal bandwidth choice gives the following result:

Theorem 1: Uniform MSE bound of N-W over Lipschitz functions

Under (K1) and (D1) with $h = \alpha n^{-1/3}$ for some $\alpha > 0$, we have

$$\sup_{m \in \text{Lipschitz}(L) \text{ on } [0,1]} \sup_{x \in [0,1]} \mathbb{E}[\hat{m}_n^{\text{NW}}(x) - m(x)]^2 \leq n^{-2/3} \cdot C,$$

for all $n \geq n_0$, where $C > 0$ depends on α, L, K_{\max} , and f_{\min} .

$$y_i = m(x_i) + \varepsilon_i$$

$$\text{Lin}([0,1]) = \left\{ m: [0,1] \rightarrow \mathbb{R} : m(x) = \beta_0 + \beta_1 x, \beta_0, \beta_1 \in \mathbb{R} \right\}$$

For $m \in \text{Lin}([0,1])$, use estimator

$$\hat{m}_n^{\text{LS}}(x) = \hat{\beta}_0 + \hat{\beta}_1 x, \quad \hat{\beta}_0, \hat{\beta}_1 \text{ are LS estimators.}$$

Then

$$\text{MSE } \hat{m}_n^{\text{LS}}(x) = \text{Var}(\hat{\beta}_0 + \hat{\beta}_1 x)$$

$$= \sigma^2 \left[\frac{1}{n} + \frac{(x - \bar{x}_n)^2}{\sum_{i=1}^n (x_i - \bar{x}_n)^2} \right]$$
$$= \frac{\sigma^2}{n} \left[1 + \frac{(x - \bar{x}_n)^2}{\underbrace{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x}_n)^2}_{= S_{\min} > 0}} \right]$$

$$\leq \frac{\sigma^2}{n} \left[1 + \frac{(x - \bar{x}_n)^2}{S_{\min}} \right]$$

Consider the MSE bound for $\hat{m}_n^{\text{Lin}}(x) = \hat{\beta}_0 + \hat{\beta}_1 x$, where

$$(\hat{\beta}_0, \hat{\beta}_1) = \underset{\beta_0, \beta_1}{\operatorname{argmin}} \sum_{i=1}^n [Y_i - (\beta_0 + \beta_1 X_i)]^2.$$

We need one assumption:

(D1lin) Let $X_1, \dots, X_n \in [0, 1]$ be deterministic such that for some $n_0 > 0$

$$n^{-1} \sum_{i=1}^n (X_i - \bar{X}_n)^2 \geq S_{\min} > 0 \text{ for all } n \geq n_0.$$

Uniform MSE bound for simple linear regression

Under (D1lin), for $n \geq n_0$, we have

$$\sup_{m \in \text{Lin}([0,1])} \sup_{x \in [0,1]} \mathbb{E} \left[\hat{m}_n^{\text{Lin}}(x) - m(x) \right]^2 \leq \frac{\sigma^2}{n} \cdot \left[1 + \frac{1}{S_{\min}} \right].$$

Exercise: Prove the above result and discuss.

Want a pivotal quantity ...

If
$$\frac{\hat{m}_n^{NW}(x) - m(x)}{\hat{\sigma}_e \{ \hat{m}_n^{NW}(x) \}} \stackrel{?}{\underset{\text{approx}}{\sim}} N(0,1)$$

Then an approximate $(1-\alpha) \cdot 100\%$ C.I. for $m(x)$ is

$$\hat{m}_n^{NW}(x) \pm z_{\alpha/2} \hat{\sigma}_e \{ \hat{m}_n^{NW}(x) \}$$

First,
$$\text{Var}(\hat{m}_n^{NW}(x)) = \text{Var}\left(\sum_{i=1}^n W_{ni}(x) Y_i\right)$$

$$= \sigma^2 \sum_{i=1}^n W_{ni}^2(x)$$

So consider this:

$$\frac{\hat{m}_n^{NW}(x) - m(x)}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}} = \underbrace{\frac{\hat{m}_n^{NW}(x) - \mathbb{E} \hat{m}_n^{NW}(x)}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}}}_{\text{Variance term}} + \underbrace{\frac{\mathbb{E} \hat{m}_n^{NW}(x) - m(x)}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}}}_{\text{bias term}}$$

$\xrightarrow{p} N(0,1)$

$\rightarrow 0$

as $n \rightarrow \infty$ under the right choice of h_n .

We have
$$\hat{m}_n^{NW}(x) - \mathbb{E} \hat{m}_n^{NW}(x) = \sum_{i=1}^n W_{ni}(x) Y_i - \mathbb{E} \sum_{i=1}^n W_{ni}(x) Y_i$$

$$= \sum_{i=1}^n W_{ni}(x) \varepsilon_i$$

$$\frac{\hat{m}_n^{NW}(x) - \mathbb{E} \hat{m}_n^{NW}(x)}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}}$$

=

$$\frac{\sum_{i=1}^n \overbrace{W_{ni}(x)}^{a_i} \underbrace{(\varepsilon_i / \sigma)}_{\varepsilon_i \sim N(0,1)}}{\sqrt{\sum_{i=1}^n W_{ni}^2(x)}} \xrightarrow{D} N(0,1)$$

provided

$$\frac{\max_{1 \leq i \leq n} |a_i|}{\left[\sum_{j=1}^n a_j^2 \right]^{1/2}} \rightarrow 0 \quad \text{as } n \rightarrow \infty,$$

$$\frac{\max_{1 \leq i \leq n} |W_{ni}(x)|}{\sqrt{\sum_{i=1}^n W_{ni}^2(x)}} \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

We have

$$\frac{\max_{1 \leq i \leq n} |W_{ni}(x)|}{\sqrt{\sum_{i=1}^n W_{ni}^2(x)}} = \frac{\max_{1 \leq i \leq n} \left| \frac{K\left(\frac{x_i - x}{h}\right)}{\sum_{j=1}^n K\left(\frac{x_j - x}{h}\right)} \right|}{\sqrt{\sum_{i=1}^n \frac{K^2\left(\frac{x_i - x}{h}\right)}{\left(\sum_{j=1}^n K\left(\frac{x_j - x}{h}\right)\right)^2}}}$$

$$W_{ni}(x) = \frac{K\left(\frac{x_i - x}{h}\right)}{\sum_{j=1}^n K\left(\frac{x_j - x}{h}\right)}$$

$$= \frac{\max_{1 \leq i \leq n} \left| k \left(\frac{x_i - \bar{x}}{h} \right) \right| \leq K_{\max}}{\sqrt{\sum_{i=1}^n k^2 \left(\frac{x_i - \bar{x}}{h} \right)^2}}$$

$$= \frac{K_{\max}}{\sqrt{nh} \sqrt{\frac{1}{nh} \sum_{i=1}^n k^2 \left(\frac{x_i - \bar{x}}{h} \right)^2}}$$

$$= \frac{1}{\sqrt{nh}} \frac{K_{\max}}{\sqrt{M}} \quad \approx M > 0$$

$\rightarrow 0$ if $nh \rightarrow \infty$.

We can choose $h_{opt} = C \cdot n^{-1/3}$

$$\frac{|\mathbb{E} \hat{m}_n^{NW}(x) - m(x)|}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}} = \frac{|\text{Bias } \hat{m}_n^{NW}(x)|}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}}$$

$$\leq \frac{h \cdot L}{\sigma \sqrt{\sum_{i=1}^n W_{ni}^2(x)}}$$

$$= \frac{h \cdot L}{\sigma \sqrt{\frac{\sum_{i=1}^n K^2\left(\frac{X_i - x}{h}\right)}{\left(\sum_{i=1}^n K\left(\frac{X_i - x}{h}\right)\right)^2}}}$$

$$= \frac{nh \cdot L \cdot \frac{1}{nh} \sum_{i=1}^n K\left(\frac{X_i - x}{h}\right)}{\sigma \sqrt{nh} \sqrt{\frac{1}{nh} \sum_{i=1}^n K^2\left(\frac{X_i - x}{h}\right)}}$$

$$\hat{f}_n(x) \leq f_{\max} < \infty$$

$$\geq M > 0$$

$$\leq n^{1/2} h^{3/2} \frac{L}{\sigma} \frac{f_{\max}}{\sqrt{M}}$$

$$\rightarrow 0 \quad \text{if} \quad n^{1/2} h^{3/2} \rightarrow 0$$

$$h_{\text{opt}} = C \cdot n^{-1/3} \Rightarrow n^{1/2} h_{\text{opt}}^{3/2} = n^{1/2} \left(n^{-1/3}\right)^{3/2} = 1$$

The bias term DOES NOT vanish under the MSE-optimal choice of h !!!!

Can we make a confidence interval for $m(x_0)$ for some $x_0 \in [0, 1]$?

If for some sequence $\vartheta_n(x_0)$ we have

$$(\hat{m}_n^{\text{NW}}(x_0) - m(x_0)) / \vartheta_n(x_0) \rightarrow \text{Normal}(0, 1) \text{ in dist. as } n \rightarrow \infty,$$

then the interval

$$\hat{m}_n^{\text{NW}}(x_0) \pm z_{\alpha/2} \vartheta_n(x_0)$$

would contain $m(x_0)$ with probability approaching $1 - \alpha$ as $n \rightarrow \infty$.

Since we are talking about sending $n \rightarrow \infty \dots$

Discuss: What must happen to h as $n \rightarrow \infty$ for $\hat{m}_n^{\text{NW}}(x_0)$ to be consistent?

To get the desired result sketched on the previous slide, we will use the following:

Corollary to the Lindeberg Central Limit Theorem

For a seq. of iid rvs ξ_1, ξ_2, \dots with zero mean and unit variance and a seq. of numbers a_1, a_2, \dots satisfying

$$\frac{\max_{1 \leq i \leq n} |a_i|}{\left[\sum_{j=1}^n a_j^2 \right]^{1/2}} \rightarrow 0 \quad \text{as } n \rightarrow \infty,$$

we have

$$\frac{\sum_{i=1}^n a_i \cdot \xi_i}{\left[\sum_{j=1}^n a_j^2 \right]^{1/2}} \rightarrow \text{Normal}(0, 1) \text{ in dist. as } n \rightarrow \infty.$$

$\text{Var} \left(\sum_{i=1}^n a_i \xi_i \right) = \sum_{i=1}^n a_i^2$

This CLT is highly useful in regression contexts.

Theorem 1: Asymptotic behavior of N-W under Lipschitz smoothness

Assume (K1) and let $X_1, \dots, X_n \in [0, 1]$ be deterministic such that for any sequence $h_n \rightarrow 0$ and $nh_n \rightarrow \infty$ there exists $n_0 > 0$ such that

$$\frac{1}{nh_n} \sum_{i=1}^n K^2 \left(\frac{X_i - x}{h_n} \right) \geq M > 0 \quad \text{and} \quad \frac{1}{nh_n} \sum_{i=1}^n K \left(\frac{X_i - x}{h_n} \right) \leq f_{\max} < \infty$$

for all $x_0 \in [0, 1]$ for all $n \geq n_0$. Then for $m \in \text{Lipschitz}([0, 1])$, we have

$$\textcircled{1} \quad \frac{\hat{m}_n^{\text{NW}}(x_0) - \mathbb{E}\hat{m}_n^{\text{NW}}(x_0)}{\sigma \left[\sum_{i=1}^n W_{ni}^2(x_0) \right]^{1/2}} \rightarrow \text{Normal}(0, 1) \text{ as } n \rightarrow \infty.$$

$$\textcircled{2} \quad \frac{|\mathbb{E}\hat{m}_n^{\text{NW}}(x_0) - m(x_0)|}{\sigma \left[\sum_{i=1}^n W_{ni}^2(x_0) \right]^{1/2}} \leq n^{1/2} h_n^{3/2} \cdot \frac{f_{\max} \cdot L}{\sigma \cdot M} \text{ for all } n \geq n_0.$$

*Choose on purpose
h smaller than h_{opt}
(Make your estimator
too wiggly
on purpose.)*

Exercise: Prove result, but discuss: Can we choose h_{opt} ? Do **undersmoothing**...

How to estimate σ^2 ?

$$\begin{aligned}
 \mathbb{E} \left(y_{(i+1)} - y_{(i)} \right)^2 &= \mathbb{E} \left(\left(\mu(x_{(i+1)}) + \epsilon_{(i+1)} \right) - \left(\mu(x_{(i)}) + \epsilon_{(i)} \right) \right)^2 \\
 &= \mathbb{E} \left(\left(\mu(x_{(i+1)}) - \mu(x_{(i)}) \right) + \left(\epsilon_{(i+1)} - \epsilon_{(i)} \right) \right)^2 \\
 &= \left(\mu(x_{(i+1)}) - \mu(x_{(i)}) \right)^2 \\
 &\quad + \mathbb{E} \left(\epsilon_{(i+1)} - \epsilon_{(i)} \right)^2 \\
 &\quad + 2 \mathbb{E} \left(\mu(x_{(i+1)}) - \mu(x_{(i)}) \right) \left(\epsilon_{(i+1)} - \epsilon_{(i)} \right) \\
 &= \underbrace{\left(\mu(x_{(i+1)}) - \mu(x_{(i)}) \right)^2}_{\leq L^2 |x_{(i+1)} - x_{(i)}|^2} + 2\sigma^2
 \end{aligned}$$

Try

$$\hat{\sigma}^2 = \frac{1}{2(n-1)} \sum_{i=1}^{n-1} (Y_{(i+1)} - Y_{(i)})^2$$

Then

$$\mathbb{E} \hat{\sigma}^2 = \sigma^2 + \underbrace{\frac{1}{2(n-1)} \sum_{i=1}^{n-1} \left(h(X_{(i+1)}) - h(X_{(i)}) \right)^2}_{}$$

$$\leq \frac{1}{2(n-1)} \sum_{i=1}^n L^2 |X_{(i+1)} - X_{(i)}|^2$$

$$X_1, \dots, X_n \in [0, 1]$$

$$\leq \frac{1}{2(n-1)} \sum_{i=1}^n L^2 |X_{(i+1)} - X_{(i)}|$$

$$\leq \frac{1}{2(n-1)} L^2 \rightarrow 0 \text{ as } n \rightarrow \infty.$$

Table of Contents

- 3 Pointwise confidence intervals
- 4 Variance estimation**
- 5 Crossvalidation for bandwidth selection
- 6 Local polynomial estimators

We now consider estimating σ^2 .

Estimator of σ^2

Let $(X_{(1)}, Y_{(1)}), \dots, (X_{(n)}, Y_{(n)})$ be the data reordered st $X_{(1)} < X_{(2)} < \dots < X_{(n)}$.
Rice (1984) [1] suggested the estimator

$$\hat{\sigma}_n^2 = \frac{1}{2(n-1)} \sum_{i=1}^{n-1} (Y_{(i+1)} - Y_{(i)})^2.$$

Consistency of differencing estimator under Lipschitz smoothness

If $X_1, \dots, X_n \in [0, 1]$, $\mathbb{E}\varepsilon_1^4 < \infty$, and $m \in \text{Lipschitz}(L)$ on $[0, 1]$,

$$\hat{\sigma}_n^2 \rightarrow \sigma^2 \text{ in prob. as } n \rightarrow \infty.$$

Exercise: Show that $\mathbb{E}\hat{\sigma}_n^2 \rightarrow \sigma^2$ as $n \rightarrow \infty$. Discuss how to prove consistency.

Finally, we can construct a confidence interval for $m(x_0)$:

Approximate $(1 - \alpha)100\%$ confidence interval for $m(x_0)$

Under the conditions of Theorem 1 and if $\mathbb{E}\varepsilon_1^4 < \infty$, we have

$$P \left(m(x_0) \in \left(\hat{m}_n^{\text{NW}}(x_0) \pm z_{\alpha/2} \hat{\sigma}_n \left[\sum_{i=1}^n W_{ni}^2(x_0) \right]^{1/2} \right) \right) \rightarrow 1 - \alpha$$

as $n \rightarrow \infty$, provided $n^{1/2} h_n^{3/2} \rightarrow 0$ and $nh_n \rightarrow \infty$, i.e. $n^{-1} \ll h_n \ll n^{-1/3}$.

I have used $a_n \ll b_n$ to mean $a_n/b_n \rightarrow 0$ as $n \rightarrow \infty$.

Discuss: How do we “undersmooth” to build confidence intervals in practice?

- Maybe we don't.

What about confidence bands?? We'll do this later with the bootstrap.

Table of Contents

- 1 Nonparametric regression

- 3 Pointwise confidence intervals
- 4 Variance estimation
- 5 Crossvalidation for bandwidth selection**
- 6 Local polynomial estimators

Crossvalidation to select h : Define the *crossvalidation prediction risk* as

$$CV_n(h) = \frac{1}{n} \sum_{i=1}^n [Y_i - \hat{m}_{n,-i}(X_i)]^2,$$

where $\hat{m}_{n,-i}$ is an estimator of m computed after removing the pair (X_i, Y_i) .

Cheaper computation of crossvalidation prediction risk

For any estimator \hat{m} of m with the form $\hat{m}_n(x) = \sum_{i=1}^n W_{ni}(x) Y_i$, we have

$$CV_n(h) = \frac{1}{n} \sum_{i=1}^n \left[\frac{Y_i - \hat{m}_n(X_i)}{1 - W_{ni}(X_i)} \right]^2.$$

The above will work for many estimators—not just the N-W.

Table of Contents

- 1 Nonparametric regression
- 2 The Nadaraya-Watson estimator
- 3 Pointwise confidence intervals
- 4 Variance estimation
- 5 Crossvalidation for bandwidth selection
- 6 Local polynomial estimators**

$$m_2(x) = \underbrace{m(x_0)}_{a_0} + \underbrace{m'(x_0)}_{a_1} (x-x_0) + \underbrace{\frac{m''(x_0)}{2}}_{a_2} (x-x_0)^2$$

Consider, for x' close to x , an order- ℓ polynomial approximation

$$m(x') \approx a_0 + a_1(x' - x) + \cdots + a_\ell \frac{(x' - x)^\ell}{\ell!}.$$

Idea: estimate a_0, a_1, \dots, a_ℓ “locally” for each x .

Local polynomial (LP) estimator

The *LP estimator of order- ℓ* of m is given by $\hat{m}_{n,\ell}^{\text{LP}}(x) = \hat{a}_0(x)$, where this is the first element of the vector

$$(\hat{a}_0, \hat{a}_1, \dots, \hat{a}_\ell)(x) = \underset{a_0, a_1, \dots, a_\ell \in \mathbb{R}}{\operatorname{argmin}} \sum_{i=1}^n \left[Y_i - \sum_{j=0}^{\ell} a_j \frac{(X_i - x)^j}{j!} \right]^2 \cdot K \left(\frac{X_i - x}{h} \right).$$

for some kernel function K and bandwidth $h > 0$.

Discuss: How is the N-W a special case of this?

NW: $l=0$

$$\hat{a}_0 = \operatorname{argmin}_{a_0 \in \mathbb{R}} \sum_{i=1}^n [y_i - a_0]^2 K\left(\frac{x_i - x}{h}\right)$$

$$\vdots$$

$$= \frac{\sum_{i=1}^n y_i K\left(\frac{x_i - x}{h}\right)}{\sum_{i=1}^n K\left(\frac{x_i - x}{h}\right)}$$

Write $\hat{m}_{n,g}^{\text{LSP}}(x) = \sum_{i=1}^n W_{ni}(x) y_i$

$$(y - U_x a)^T K_x (y - U_x a)$$

$$(\hat{a}_0, \hat{a}_1, \dots, \hat{a}_\ell)(x) = \operatorname{argmin}_{a_0, a_1, \dots, a_\ell \in \mathbb{R}} \sum_{i=1}^n \left[y_i - \sum_{j=0}^{\ell} a_j \frac{(x_i - x)^j}{j!} \right]^2 \cdot K\left(\frac{x_i - x}{h}\right)$$

$$\tilde{y} = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix}$$

$$U_x = \begin{bmatrix} 1 & x_1 - x & \dots & \frac{(x_1 - x)^\ell}{\ell!} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_n - x & \dots & \frac{(x_n - x)^\ell}{\ell!} \end{bmatrix}$$

$$\tilde{a} = \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_\ell \end{bmatrix}$$

$$K_x = \operatorname{diag}\left(K\left(\frac{x_1 - x}{h}\right), \dots, K\left(\frac{x_n - x}{h}\right)\right)$$

Then we can show

$$\hat{\tilde{a}}_x = \left(U_x^T K_x U_x \right)^{-1} U_x^T K_x \tilde{y}$$

$$\hat{m}_n^{LP}(x) = e_{\tilde{1}}^T \hat{\tilde{a}}_x \quad e_{\tilde{1}}^T = (1, 0 \dots 0)$$

$$= e_{\tilde{1}}^T \left(U_x^T K_x U_x \right)^{-1} U_x^T K_x \tilde{y}$$

Find $W_{ni}(x)$, $i=1, \dots, n$ s.t. that $\hat{m}_n^{LP}(x) = \sum_{i=1}^n W_{ni}(x) y_i$.

$$\hat{m}_n^{LP}(x) = e_{\tilde{1}}^T \left(U_x^T K_x U_x \right)^{-1} U_x^T K_x \tilde{y}$$

$$= e_{\tilde{1}}^T \left(U_x^T K_x U_x \right)^{-1} \begin{bmatrix} 1 & \dots & 1 \\ x_1 - x & \dots & x_n - x \\ \vdots & \ddots & \vdots \\ \frac{(x_1 - x)^2}{2!} & \dots & \frac{(x_n - x)^2}{2!} \end{bmatrix} \begin{bmatrix} k\left(\frac{x_1 - x}{h}\right) \\ \vdots \\ k\left(\frac{x_n - x}{h}\right) \end{bmatrix} \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix}$$

$$= \sum_{i=1}^n e_{\tilde{1}}^T \left(U_x^T K_x U_x \right)^{-1} \begin{bmatrix} 1 \\ x_i - x \\ \vdots \\ \frac{(x_i - x)^2}{2!} \end{bmatrix} k\left(\frac{x_i - x}{h}\right) y_i$$

$$\Rightarrow W_{ni}(x) = e_{\tilde{1}}^T \left(U_x^T K_x U_x \right)^{-1} \begin{bmatrix} 1 \\ x_i - x \\ \vdots \\ \frac{(x_i - x)^2}{2!} \end{bmatrix} k\left(\frac{x_i - x}{h}\right)$$

OR :

$$\hat{\tilde{a}}_x = (U_x^T K_x U_x)^{-1} U_x^T K_x \tilde{y}$$

$$= L_x^T \tilde{y}$$

$$L_x = K_x U_x (U_x^T K_x U_x)^{-1}$$

$$\hat{a}_0(x) = e_{\tilde{1}}^T L_x^T \tilde{y}$$

$$= (L_x e_{\tilde{1}})^T \tilde{y},$$

So

$$\tilde{w}_x = \begin{bmatrix} w_{n_1}(x) \\ \vdots \\ w_{n_n}(x) \end{bmatrix} = L_x e_{\tilde{1}}.$$

Exercise:

- 1 Find matrices \mathbf{U}_x and \mathbf{K}_x and the vector \mathbf{Y} such that

$$\hat{\mathbf{a}}(x) = (\hat{a}_0, \hat{a}_1, \dots, \hat{a}_\ell)(x)^T = (\mathbf{U}_x^T \mathbf{K}_x \mathbf{U}_x)^{-1} \mathbf{U}_x^T \mathbf{K}_x \mathbf{Y}.$$

- 2 Find an expression for weights $W_{ni}^*(x)$ such that

$$\hat{m}_{n,\ell}^{\text{LP}}(x) = \sum_{i=1}^n W_{ni}^*(x) Y_i.$$

Tsybakov [2] gives the following result (we omit the details of the assumptions)

Theorem 2: Uniform MSE bound for LP over Hölder functions

Under conditions in Tsybakov, if $m \in \mathcal{H}(\beta, L)$, the order- ℓ LP estimator satisfies

$$\sup_{m \in \mathcal{H}(\beta, L)} \sup_{x \in [0, 1]} \underbrace{\mathbb{E}[\hat{m}_{n, \ell}^{\text{LP}}(x) - m(x)]^2}_{\text{MSE } \hat{m}_{n, \ell}^{\text{LP}}(x)} \leq n^{-\frac{2\beta}{2\beta+1}} \cdot C$$

for large enough n , where $\ell = \beta - 1$.

$\Rightarrow \beta = 2$, use local linear, LP ($\ell = 1$), get $n^{-\frac{4}{5}}$

Discuss:

- 1 Compare this to our N-W results under Lipschitz smoothness.
- 2 What does a larger β mean for the rate of convergence?
- 3 What is the interpretation of larger β ?

Much nonparametric regression lit. is written under the settings of this theorem:

Theorem 3: MSE of N-W, LP-1 under bounded 2nd derivative

Let X_1, \dots, X_n have continuous and differentiable density f , and x st $f(x) > 0$; set $\kappa^2 = \int_{\mathbb{R}} K^2(u) du$, $\mu_2(K) = \int_{\mathbb{R}} u^2 K(u) du$; suppose m'' is continuous and bounded. Then for $h \rightarrow 0$ and $nh \rightarrow \infty$ as $n \rightarrow \infty$, we have

$$\text{Bias } \hat{m}_n^{\text{NW}}(x) = \frac{h^2}{2} \left[m''(x) + 2 \frac{m'(x)f'(x)}{f(x)} \right] \mu_2(K) + o_p(h^2)$$

$$\text{Bias } \hat{m}_{n,1}^{\text{LP}}(x) = \frac{h^2}{2} m''(x) \mu_2(K) + o_p(h^2),$$

local-linear ($q=1$)

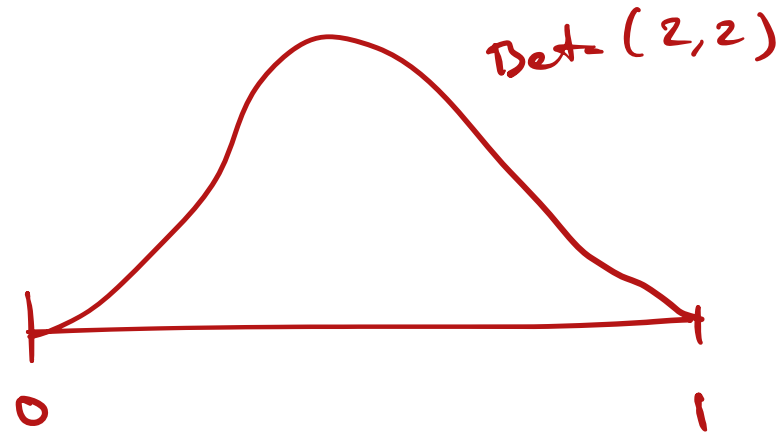

while $\text{Var } \hat{m}_n^{\text{NW}}(x)$ and $\text{Var } \hat{m}_{n,1}^{\text{LP}}(x)$ are both given by $\frac{1}{nh} \frac{\sigma^2}{f(x)} \kappa^2 + o_p((nh)^{-1})$.

See Wasserman book [3].

Discuss: Insights from above. Curvature, design bias, optimal rate, etc.

Illustration: In the next four slides, we have

- $X_1, \dots, X_n \stackrel{\text{ind}}{\sim} \text{Beta}(2, 2)$.
- $n = 300, h = 0.1$.
- N-W and local linear (LP-1) estimators fit on 50 simulated data sets.
- Four different choices of the function m .

Goal: Compare bias and variance of against the result in the previous slide
